Abstract. New heavy resonances are predicted by many extensions of the standard model of particle physics. Recent results for high mass resonance searches with the Compact Muon Solenoid detector, in the diphoton, dilepton, dijet, and $\bar{t}t$ channels, are discussed. Limits for numerous benchmark models are presented.

1 Introduction

We present recent results for high mass resonance searches with the Compact Muon Solenoid (CMS) detector. The searches are conducted in a model independent manner, looking for excesses in the diphoton, dilepton, dijet, and $\bar{t}t$ invariant mass spectra. As no excesses above standard model (SM) expectations are observed, limits are computed, probing a variety of benchmark models, such as those predicting Randall-Sundrum (RS) gravitons, extra heavy gauge bosons ($Z', W'$), and other exotic phenomena.

2 The CMS Detector

The central feature of the CMS apparatus is a superconducting solenoid, of 6m internal diameter, providing a field of 3.8 T. Within the field volume are the silicon pixel and strip tracker, the crystal electromagnetic calorimeter (ECAL) and the brass and scintillator hadron calorimeter (HCAL). Muons are measured in gas-ionization detectors embedded in the steel return yoke. In addition to the barrel and endcap detectors, CMS has extensive forward calorimetry. A more detailed description can be found in Ref. [3].

3 Diphoton Resonances

Kaluza-Klein (KK) gravitons predicted by RS warped extra dimensions may manifest themselves as high mass resonances in the diphoton invariant mass spectrum. The diphoton channel has the advantage that the branching ratio for spin-2 gravitons is twice that to leptons. Two isolated photons are selected with $E_T > 70$ GeV and $|\eta| < 1.44$. The resulting diphoton invariant mass distribution with $2.2 \text{fb}^{-1}$ of data is shown in Fig. 1. The expected background arising from irreducible SM diphoton production is estimated using simulation, scaled by a next-to-leading order mass dependent $K$ factor. Instrumental backgrounds, arising from $\gamma+\text{jet}$ and dijet processes, in which the jets are misidentified as photons, are estimated using a data-driven fake rate method. Observing no excess in the diphoton invariant mass distribution above SM expectations, upper limits are set on the production cross section for RS gravitons, using the CL$_S$ technique [5,6]. The limits on the cross section are translated into lower limits on the model parameters (Fig. 2), where $M_1$ is the mass of the first graviton excitation, and $k$ is a dimensionless parameter which quantifies the strength of the graviton coupling to SM fields. We exclude at the 95% confidence level (CL) resonant graviton production in the RS1 model with values of $M_1 < 0.86 - 1.84$ TeV, depending on $k$.

4 Dilepton Resonances

High mass dilepton resonances may arise in models with extra heavy gauge bosons, as well as in the RS warped extra dimension scenario. In this search, two isolated leptons with $p_T > 35$ GeV (40 GeV for endcap electrons) are required, in addition to further quality criteria. In the case of dimuons, opposite-sign is required. The resulting dielec-

The 95% CL exclusion region for the RS1 graviton model in the $M_t$-$k$ plane. The expected limits coincide very closely with the measured limits and so are not shown in the figure. Also shown are bounds due to electroweak constraints and naturalness ($\Lambda_k > 10$ TeV). Perturbativity requirements bound $k < 0.10$.

Fig. 2. Invariant mass spectrum of $\mu^+\mu^-$ (top) and $ee$ (bottom) events. Data is represented by points with error bars. The uncertainties on the data points (statistical only) represent 68% confidence intervals for the Poisson means. The filled histograms represent the expectations from SM processes.

Fig. 3. The dilepton analysis is a shape-based search, making no assumptions on the absolute background rate; this is achieved by normalizing the results to the $Z^0$ peak in data. We set limits, using a Bayesian technique, on the ratio ($R_e$) of the cross section for $Z'$ (or $G_{KK}$) production to the cross section for SM $Z^0$ production (Fig. 4). The limits on $R_e$ can be interpreted as lower limits on $Z'$ ($G_{KK}$) mass. We exclude at 95% CL a $Z'$ with SM-like couplings ($Z'_{\text{SM}}$) with mass less than 1940 GeV, the superstring-inspired $Z'_0 < 1620$ GeV, and RS $G_{KK} < 1450$ (1780) GeV for $k = 0.05$ (0.10).

Fig. 4. Upper limits on the production ratio $R_e$ of cross section times branching fraction into lepton pairs as a function of resonance mass, for $Z'_{\text{SM}}$, $Z'$, and $G_{KK}$. The limits are shown from the combined dilepton ($ee + \mu^+\mu^-$) result. Shaded yellow and red bands correspond to the 68% and 95% quantiles for the expected limits. The predicted cross section ratios are shown in bands, with widths indicating theoretical uncertainties.

5 Dijet Resonances

Dijets can be used to probe a variety of beyond-the-SM signatures, including string resonances [8], $E_6$ diquarks [9], excited quarks [10], axigluons [11], colorons [12], $W'$ and $Z'$, and RS gravitons. We perform a general model independent shape-based search for three types of resonances (qq, qg, gg), the differences arising from final state radiation (FSR).

We require the two leading jets have $|\eta| < 2.5$ and $|\Delta R| < 1.3$ and dijet invariant mass $> 838$ GeV. To recover radiation lost through FSR and to improve the dijet mass resolution, we combine particle flow jets with the anti-$k_T$ algorithm ($R = 0.5$) into “wide jets”. QCD multijets comprise the main background, following a smoothly falling dijet mass distribution predicted by the SM. Fig. 5 shows the dijet invariant mass spectrum with 1.0 fb$^{-1}$, where the expected background from QCD multijets is described with a functional fit [13]. The systematic uncertainties from the
Dijet mass spectrum from wide jets (points) compared to a smooth fit (solid) and to predictions including detector simulation of QCD (short-dashed), excited quark signals (dot-dashed), and string resonance signals (long-dashed). The QCD prediction has been normalized to the data. The error bars are statistical only. The shaded band shows the systematic uncertainty in the jet energy scale (JES). The bin-by-bin significance of the data-fit difference is shown at bottom.

The motivations for studying the fully hadronic decay of $t\bar{t}$ are similar to those for the semileptonic search. Likewise, the all-hadronic search exploits the highly boosted nature of the top quarks from high mass resonances. Moreover,

**6 $t\bar{t}$ Resonances: Semileptonic Decay**

New bosons with enhanced coupling to the top quark appear in many SM extensions, such as those predicting axigluons and KK gluons [15]. We present a search for heavy $t\bar{t}$ resonances in the semileptonic ($q\bar{q}b\bar{b})(\mu\nu b)$ final state, focusing on highly boosted top pairs with decay products narrowly collimated along the direction of the top. Backgrounds arise from SM $t\bar{t}$, $W/Z$+jets, single top, and QCD multijets.

For high mass $t\bar{t}$, the decay products of the hadronic-decaying top can have small opening angles in the detector frame. Thus, instead of requiring four jets, we require two particle flow jets with $p_T > 50$ GeV and $|\eta| < 2.4$, with the leading jet $p_T > 250$ GeV; jets are reconstructed with the anti-$k_T$ algorithm ($R = 0.5$). The high top $p_T$ also results in low $AR = \sqrt{(Δϕ)^2 + (Δη)^2}$ between the $μ$ and $b$, making it difficult to require the muon to be well-isolated. To suppress QCD multijet backgrounds, we thus apply a two-dimensional requirement, $AR > 0.5$ or $pT_{rel} > 25$ GeV, where $pT_{rel}$ is the magnitude of the $p_T$ component orthogonal to the jet axis. In addition, muons are required to have $p_T > 35$ GeV and $|\eta| < 2.1$. Events with additional muons or electrons (from $t\bar{t}$ and $Z'$ decays) are vetoed. Lastly, $H_{T,lep}$, the scalar sum of the muon $p_T$ and missing transverse energy (MET), is required to be $> 150$ GeV.

**Fig. 6.** The 95% CL upper limits on cross section ($\sigma$) and branching ratio ($B$) and acceptance ($A$), for dijet resonances of type gluon-gluon (open circles), quark-gluon (solid circles), and quark-quark (open boxes), compared to theoretical predictions for string resonances, $E_6$ diquarks, excited quarks, axigluons, colorons, new gauge bosons $W'$ and $Z'$, and RS gravitons.

**Fig. 7.** Expected and observed 95% CL upper limits on $\sigma(pp \to Z' \to t\bar{t})$ for narrow resonances $Z'$, as a function of invariant mass. The topcolor $Z'$ cross section is from $[17]$, updated to $\sqrt{s} = 7$ TeV via private communication.

**7 $t\bar{t}$ Resonances: All-Hadronic Decay**

The motivations for studying the fully hadronic decay of $t\bar{t}$ are similar to those for the semileptonic search. Likewise, the all-hadronic search exploits the highly boosted nature of the top quarks from high mass resonances. Moreover,
the all-hadronic decay benefits from a higher branching ratio than the semileptonic decay.

In this analysis, each event is divided into hemispheres, such that each hemisphere contains the final products of each top. Then, the top decays are classified into categories, depending on the how boosted the top is: (1) “high boost” tops are those in which all three jets are merged into one top jet and (2) “moderate boost” tops are those in which only two out of three of the jets are merged. We conduct the search in two categories: “type 1+1”, which have two highly boosted top jets, or “type 1+2”, which are three-jet events. Jets are reconstructed using particle flow and Cambridge-Aachen clustering algorithms. The dominant background comes from QCD multijets, which is estimated with a data-driven top-tagging mistag rate. The small continuum $t\bar{t}$ contribution is estimated with simulation. The limits are evaluated with a counting experiment, using a Bayesian procedure. Fig. 8 depicts the 95% CL upper limits on the product of the cross section of $Z'$ and the branching ratio for its decay into $t\bar{t}$ pairs [18]. With 886 pb$^{-1}$, we exclude the KK gluon masses between 1.0 – 1.5 TeV.

8 Conclusions

We present searches for high mass resonances with the CMS detector in the diphoton, dilepton, dijet, and $t\bar{t}$ channels. Observing no excess above standard model predictions, we set limits on a variety of benchmark models, including those predicting gravitons and $Z'$.
