**Abstract.** In our paper we report on magnetic properties of  $\text{La}_{0.9}\text{Ag}_{0.1}(\text{Co}_x\text{Mn}_{1-x})\text{O}_3$  ferromagnetic ceramics ( $x = 0.00$  and  $0.03$ ) which were studied in pressures up to  $0.9$  GPa. Magnetic transition at the Curie temperature  $T_C$  is accompanied with metal insulator transition with a maximum  $T$  which is shifted to lower temperature with applied magnetic field. The Curie temperature is decreasing with substitution of Co for Mn and is ranging from  $178$  K to  $126.5$  K. Hydrostatic pressure increases for sample with  $x = 0.03$  nearly linearly with the pressure coefficient  $dT_C/dp = 5.7$  K/GPa. Hysteresis loop is affected marginally, increases and  $\mu$  decreases with pressure.

## 1 Introduction

Recent works performed on the mixed-valence perovskite microstructure of the samples was examined by means of scanning electron microscopy. Crystallites with diameters understand and exploit the large negative magneto-resistance and magnetocaloric effects. Ca-doped lanthanum manganites were first reported during a study of ionic ferromagnets with the general composition  $\text{La}_{1-x}\text{M}_x\text{MnO}_3$ , where M was a divalent cation, e.g.  $\text{Ca}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Cd}^{2+}$  or  $\text{Pb}^{2+}$ . The compound  $\text{La}_{1-x}\text{Ca}_x\text{MnO}_3$  is a metallic ferromagnet for  $0.23 < x < 0.45$ ; for all other calcium concentrations, the ground state is insulating. Both, the mixed valence state  $\text{Mn}^{4+}$  and the double exchange (DE) interaction are needed for metallic behaviour and ferromagnetism in these materials. Replacing the divalent alkali-earth metals by monovalent elements, such as Na, K and Li, also leads to similar phenomena in manganites. Recently substitution of Ag for La in  $\text{LaMnO}_3$  leads to another series of novel oxides exhibiting ferromagnetic metal to paramagnetic insulators transition with high CMR effect at room temperature [15]. In our paper we study magnetic properties of  $\text{La}_{0.9}\text{Ag}_{0.1}(\text{Co}_x\text{Mn}_{1-x})\text{O}_3$  ferromagnetic ceramics at ambient pressure and high hydrostatic pressure.

## 2 Experimental

The preparation of the ceramic  $\text{La}_{0.9}\text{Ag}_{0.1}(\text{Mn}_{1-x}\text{Co}_x)\text{O}_{3-x}$  ( $x = 0.0$  and  $0.03$ ) followed the malic acid gel method. The solution was slowly evaporated until a gel was formed and then calcinated at  $1100^\circ\text{C}$  for  $24$  hours. The samples were compacted into discs of about  $10$  mm diameter and

a thickness of  $1$  mm with a pressure of  $50$  bar and  $67\% \text{ relative humidity}$  for  $10$  hours. The

microstructure of the samples was examined by means of scanning electron microscopy. Crystallites with diameters up to  $100$  nm were observed. Larger agglomerates can be seen in electron microscopy (Fig.1.). EDAX analysis revealed Ag particles randomly spread in ceramic. The number of particles is small and Ag - particles do not effect magnetic properties of samples. X-ray powder diffractions were measured using  $\text{Cu K}\alpha$  radiation ( $40$  kV,  $45$  mA). X-ray diffraction revealed that sample consists of a single phase which adopts rhomboedral crystal structure (space group  $R\bar{3}c$ ) with lattice parameters  $a = 0.5514(3)$  nm,  $c = 1.3338(7)$  nm for  $x = 0.0$  and  $a = 0.5515(6)$  nm,  $c = 1.3334$  nm for  $x = 0.03$  (Fig.2). Magnetization measurements were performed by a SQUID for La in  $\text{LaMnO}_3$  leads to another series of novel oxides exhibiting ferromagnetic metal to paramagnetic insulators transition with high CMR effect at room temperature [15]. In our paper we study magnetic properties of  $\text{La}_{0.9}\text{Ag}_{0.1}(\text{Co}_x\text{Mn}_{1-x})\text{O}_3$  ferromagnetic ceramics at ambient pressure and high hydrostatic pressure. During all magnetization measurements. A piston cylinder type of the CuBe pressure cell was filled up by a mixture of mineral oils serving as hydrostatic pressure transmitting medium and operating up to  $1.2$  GPa. Actual pressure was determined in-situ from the pressure dependence of the superconducting transition temperature  $T_c(p)$  of an inserted high-purity lead sample. Pressure in the clamped CuBe cell increases with increasing temperature and a correction on actual pressure at the actual temperature was made. The pressure CuBe cell is permanently present in all detecting coils of the SQUID magnetometer and hence, it practically does not

contribute to overall magnetization of the studied samples. Experimental data presented in our paper were not corrected for a signal of the pressure cell. The pressure was changed at room temperature only and the experiments were started at the highest pressure that was then gradually decreased in two or three steps. All pressure induced changes of magnetization were reversible. Electrical resistance measurements were performed by the four probe method in the PPMS equipment.

### 3 Results and discussion

Temperature dependence of resistivity which is shown in Fig.3 clearly displays the insulator metal transition at about  $T = 121$  K. The insulator metal transition appears near the magnetic phase transition. The insulator metal transition is characteristic feature of many ferromagnetic manganites  $\text{La}_{1-x}\text{M}_x\text{MnO}_3$  with perovskite like crystal structure (M is a divalent cation).

shifts  $T$  to lower temperature but the shape of resistivity maximum is not affected by magnetic field up to 9 T. This behaviour is unusual for manganites where colossal magnetoresistance appears very frequently.

Temperature dependence of magnetization which was measured in zero field cooled (ZFC) and field cooled (FC) is shown in Fig.4 for parent compound. Magnetic phase transition is accompanied by an increase of magnetization. Hysteresis behavior between magnetization measured in ZFC and FC regimes is typical feature of both samples. The  $M(T)$  curves measured in ZFC regime start to deviate from  $M(T)$  curve measured in FC regime at the bifurcation temperature  $T_b$ , which is close to magnetic phase transition. Both samples undergo paramagnetic to ferromagnetic phase transition at the Curie temperature  $T_c$  which was determined as a minimum  $dM/dT(T)$  dependence. Substitution of Co for Mn reduces  $T_c$  from 178 K to 126.5 K for  $x = 0.00$  and  $x = 0.03$ , respectively.

Both samples undergo paramagnetic to ferromagnetic phase transition at the Curie temperature  $T_c$  which was determined as a minimum  $dM/dT(T)$  dependence. Substitution of Co for Mn reduces  $T_c$  from 178 K to 126.5 K for  $x = 0.00$  and  $x = 0.03$ , respectively.

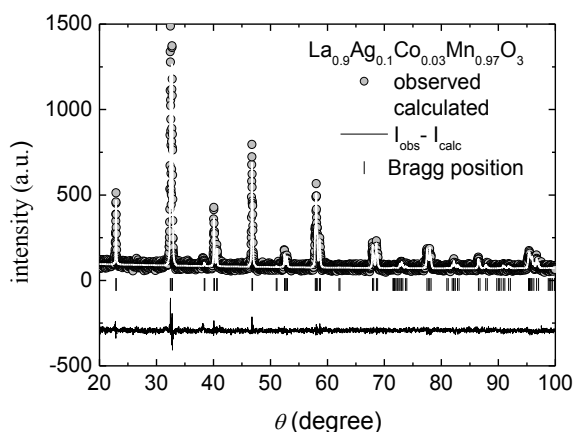

Fig.2. X-ray powder diffraction pattern from  $\text{La}_{0.90}\text{Ag}_{0.10}\text{Co}_{0.03}\text{Mn}_{0.97}\text{O}_3$  sample sintered at 1350°C for 72h. The measured points are indicated by circles, calculated by the overlaying red line. The lower curve shows the difference between the observed and calculated diffraction patterns.

Fig.4. Temperature dependence of the magnetization of  $\text{La}_{0.90}\text{Ag}_{0.10}\text{MnO}_3$  ceramic was measured in ZFC and FC regimes.

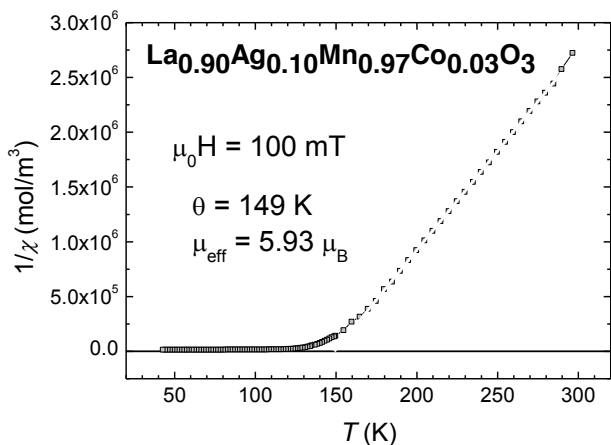

Fig.5. Temperature dependence of the inverse magnetic susceptibility for  $\text{La}_{0.90}\text{Ag}_{0.10}\text{Mn}_{0.97}\text{Co}_{0.03}\text{O}_3$ . The solid line represents fit to the Curie-Weiss law.

as it is demonstrated for sample with  $x = 0.03$  (Fig.5). The paramagnetic Curie temperature decreases with substitution from  $\theta = 181.5$  K to  $149$  K and effective magnetic moment  $\mu_{\text{eff}}$  is reduced from  $6.93 \mu_B$  to  $5.93 \mu_B$ . It is expected that in given electric crystalline field the spin of Co is zero and substitution of Co for Mn has a dilution effect; the number of Mn ions is smaller and double exchange which is dominantly responsible for ferromagnetic ordering is weaker. The value of  $\mu_{\text{eff}}$  is very high in comparison with magnetic moment of  $\text{Mn}^{3+}$  ( $4.90$ ) or  $\text{Mn}^{4+}$  ( $3.87 \mu_B$ ) and at present we do not have any explanation for this fact.

Fig.6. displays temperature dependences of magnetization measured in ZFC and FC regimes for sample with  $x = 0.03$  under different pressures. At ambient pressure, the sample undergoes the transition from paramagnetic to ferromagnetic state at  $T_C = 126.5$  K. Under hydrostatic pressure  $T_C$  increases almost linearly with the slope of a linear fit  $dT_C/dp = +5.7$  K/GPa (Fig.7.). This pressure parameter is small in comparison

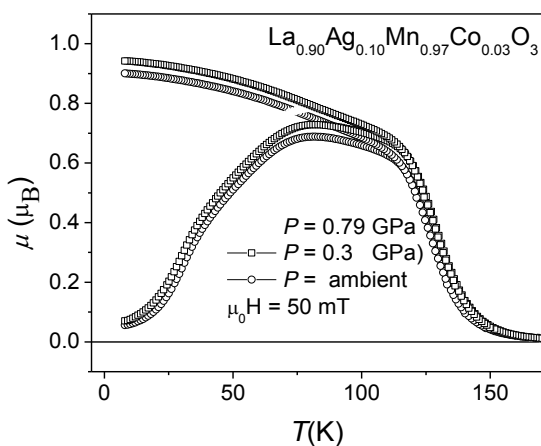

Fig.6. Temperature dependence of the magnetization which was measured in FC regime and in ZFC regime on  $\text{La}_{0.90}\text{Ag}_{0.10}\text{Mn}_{0.97}\text{Co}_{0.03}\text{O}_3$  is shown for different value of hydrostatic pressure.

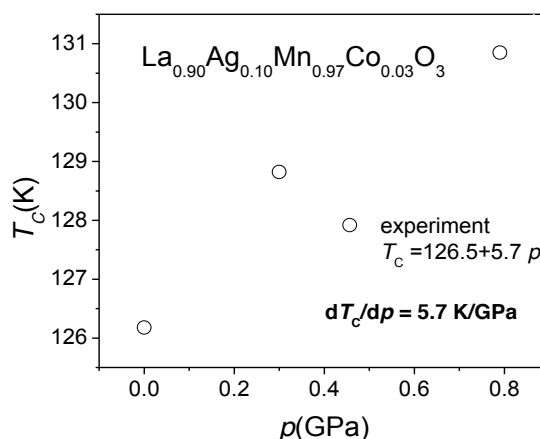

Fig. 7. The Curie temperature  $T_C$  of ceramic with  $x = 0.03$  is shown as a function of pressure.

to the same parameters obtained usually on manganites which can reach value of about  $dT_C/dp = +23.4$  K/GPa as it was determined for  $\text{La}_{0.97}\text{Ca}_{0.03}\text{Mn}_{0.97}\text{Co}_{0.03}\text{O}_3$  ceramic prepared by the same technique [1]. The increase of  $T_C$  is usually attributed to the pressure induced increase of the electronic band width  $W$  due to increase of the bonding angle and reduction of the bond length of Mn-O-Mn. Magnetization measured in both ZFC and FC regimes increases with applied pressure. Effect of pressure on saturated magnetization is small (Fig.8). Hysteresis loops shows a typical ferromagnetic state but magnetization does not saturate even at  $3$  T. Applied pressure reduces a coercivity force at about 30% and increases  $\mu_s$  at about 5 % per 1 GPa.

In conclusion,  $\text{La}_{0.90}\text{Ag}_{0.10}(\text{Mn}_{1-x}\text{Co}_x)\text{O}_3$  ferromagnetic ceramics ( $x = 0.0$  and  $0.03$ ) were synthesized by a sol gel method. The Curie temperature ranging from  $178$  K to  $126.5$  K is decreasing with substitution of Co for Mn. The Curie temperature  $T_C$  increases almost linearly with applied pressure with the slope of a linear fit  $dT_C/dp = +5.7$  K/GPa and the coercive force decreases at about 30% per GPa.

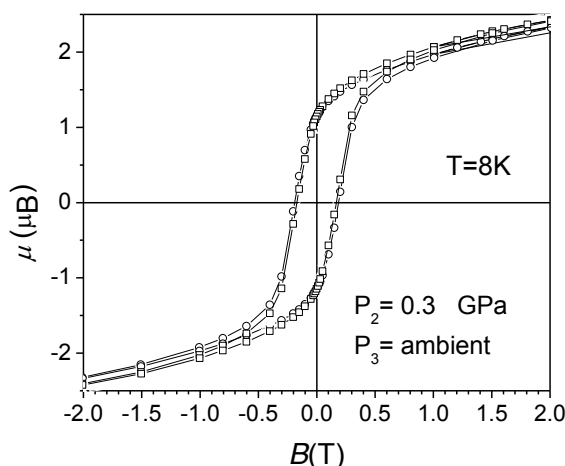

Fig.8. Hysteresis loops of  $\text{La}_{0.90}\text{Ag}_{0.10}\text{Mn}_{0.97}\text{Co}_{0.03}\text{O}_3$  ceramic were measured at  $8$  K for three for different pressures.
