OPE of Green functions in the odd sector of QCD

T. Kadavý, K. Kampf, and J. Novotný

Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic

Abstract. A review of familiar results of the three-point Green functions of currents in the odd-intrinsic parity sector of QCD is presented. Such Green functions include very well-known examples of \( VVP \), \( VAS \) or \( AAP \) correlators. We also present new results for \( VVA \) and \( AAA \) Green functions that have not yet been studied extensively in the literature before, more importantly with a phenomenological study and a discussion of the high-energy behaviour and its relation to the QCD condensates.

1 Introduction

The Green functions are defined as the vacuum expectation values of the time ordered products of the composite operators \( O(x_i) \). In the momentum representation, the standard definition of the three-point Green functions reads

\[
\int d^4x_1 \ d^4x_2 \ e^{i(p_1 x_1 + p_2 x_2)} \langle 0 | [O_1(x_1) O_2(x_2) O_3(0)] | 0 \rangle.
\]

In our case, the composite operators \( O(x_i) \) stand either for chiral vector \( V^\mu a = \overline{q} \gamma^\mu T^a q \) and axial-vector \( A^\mu a = \overline{q} \gamma^\mu \gamma^5 T^a q \) currents, or scalar \( S^a = \overline{q} T^a q \) and pseudoscalar \( P^a = \overline{q} \gamma_5 T^a q \) densities, where \( q \) stands for the quark triplet that contains the light quarks \( (u,d,s) \), \( T^a \) is a SU(3) generator, \( T^a = \lambda^a / 2 \), and \( a = 1 \ldots 8 \) are the group indices. Obviously, all the group and Lorentz indices in the definition above are suppressed for simplicity.

As we mentioned above, there exist only five nontrivial three-point Green functions in the odd parity sector of QCD. The nonvanishing combinations of currents and densities are the following: \( VVP \), \( VAS \), \( AAP \), \( VVA \) and \( AAA \). There are two regimes where the QCD dynamics of the current correlators is well understood.

The first one is that of low external momenta where the dynamics is governed by the approximate chiral symmetry of low-energy QCD. In detail, the spontaneous breaking of the chiral SU(3)_L \( \times \) SU(3)_R symmetry down to SU(3)_V in QCD leads to the presence of Goldstone bosons. By identifying them with the octet of pseudoscalar mesons \( (\pi,K,\eta) \) as the lightest hadronic observable states, we can construct chiral perturbation theory (\( \chi \)PT) as an effective theory of QCD for energies \( E \leq M_\rho \), where \( M_\rho \) is the mass of the rho meson \cite{1}, \cite{2}, \cite{3}. For energies \( M_\rho \leq E \leq 2 \) GeV the effective theory is resonance chiral theory (\( R_\chi \)T) \cite{4}. Such theory increases the number of degrees of freedom of \( \chi \)PT by including massive U(3) multiplets of vector \( V(1^-) \), axial-vector \( A(1^+) \), scalar \( S(0^+) \) and pseudoscalar \( P(0^-) \) resonances.

The second regime corresponds to the high energies where the asymptotic freedom allows us to use the perturbative approach in terms of the strong coupling $\alpha_s$ and where the asymptotics of the correlators for large Euclidean momenta is given by the operator product expansion (OPE). Within the OPE framework, short-distance behaviour of the Green functions can be studied. For example, let us consider a product of two operators $A(x)$ and $B(y)$. Then, the OPE is equivalent to an assumption that at large external momentum $p$, the two-point Green function of the operators above can be rewritten in the form

$$
 i \int d^4x \, e^{ipx} \langle 0 \big| T[A(x)B(y)] \big| 0 \rangle = \sum_n C_n^{AB}(p^2) \langle 0 | O_n | 0 \rangle ,
$$

where $\langle 0 | O_n | 0 \rangle$ are the vacuum averages of composite gauge-invariant local operators, made of quark and gluon fields. Note that only the spin-zero operators contribute to the vacuum expectation value. Such vacuum averages are usually called the QCD condensates. Considering the dimension of such condensates to be $D \leq 6$, their complete set in massless theory is as follows:

- the unit operator: $O_0 = 1$, \hspace{1cm} (3)
- quark condensate: $O_3 = \langle 0 | q \bar{q} | 0 \rangle$, \hspace{1cm} (4)
- gluon condensate: $O_4 = \langle 0 | G_{\mu
u} G^{\mu\nu} | 0 \rangle$, \hspace{1cm} (5)
- quark-gluon condensate: $O_5 = \langle 0 | q \sigma_{\mu\nu} G^{\mu\nu} q | 0 \rangle$, \hspace{1cm} (6)
- four-quark condensate: $O_6^q = \langle 0 | \bar{q} \Gamma q | 0 \rangle$, \hspace{1cm} (7)
- three-gluon condensate: $O_6^G = \langle 0 | G_{\mu\nu} G_{\rho\sigma} G^{\mu\nu} | 0 \rangle$, \hspace{1cm} (8)

where $\Gamma$ stands for any combination of the $4 \times 4$ matrices of a set $\{1, \gamma_5, \gamma^\mu, \gamma_5 \gamma^\mu, \sigma^\mu\nu\}$ together with the $3 \times 3$ matrices $\{1, T^a\}, a = 1 \ldots 8$, that is Lorentz invariant. In the following sections we will see that such QCD condensates play an important role in evaluation of the OPE of the corresponding Green functions.

It seems that the three-point OPE has been known only for three out of five nontrivial Green functions in the odd-intrinsic parity sector of QCD, specifically for $VVP$, $VAS$ and $AAP$. Therefore, the study of the OPE for $VVA$ and $AAA$ correlators is thus given by our contribution.

### 1.1 Notation

In this article, we consider all momenta $p, q, r$ as ingoing to the vertices, i.e. the law of momentum conservation can be written in the form

$$
 p + q + r = 0 .
$$

Also, a notation for the contractions of Levi-Civita tensor with the four-momenta is defined as

$$
 \epsilon_{\mu\nu\alpha\beta}(p) \equiv \epsilon_{\mu\nu\alpha\beta} p^\alpha q^\beta , \quad \epsilon_{\mu\nu\alpha\beta}(p|q) \equiv \epsilon_{\mu\nu\alpha\beta} p^\alpha q^\beta . \hspace{1cm} (10)
$$

### 2 Review of familiar results

As we have already mentioned, the Green functions that have been already studied extensively in the literature are $VVP$, $VAS$ and $AAP$. All three of them can be written in the simple forms

$$
 (\Pi_{VVP}(p, q; r))^{abc}_{\mu\nu} = \Pi_{VVP}(p^2, q^2, r^2) \epsilon^{abc} \epsilon_{\mu\nu}(p|q) , \hspace{1cm} (11)
$$

$$
 (\Pi_{VAS}(p, q; r))^{abc}_{\mu\nu} = \Pi_{VAS}(p^2, q^2, r^2) \epsilon^{abc} \epsilon_{\mu\nu}(p|q) , \hspace{1cm} (12)
$$

$$
 (\Pi_{AAP}(p, q; r))^{abc}_{\mu\nu} = \Pi_{AAP}(p^2, q^2, r^2) \epsilon^{abc} \epsilon_{\mu\nu}(p|q) . \hspace{1cm} (13)
$$

2
The high-energy behaviour within the OPE framework can be written down as follows. If we consider all individual external momenta of all the three currents or densities to be high, it is easy to realize that the leading order contribution corresponds to two contractions of the quark fields contained in the respective currents and densities. The next-to-leading order resonance Lagrangian, relevant in the odd-intrinsic parity sector of QCD, to be saturated by the resonant states at low energies. This assumption connects the LECs to the properties of the corresponding spectral functions in terms of the chiral sum rules. These are usually assumed to be saturated by the resonant states at low energies. This assumption connects the LECs to the phenomenology of resonances in the intermediate energy region, i.e. for energies \( M_\rho \leq E \leq 2 \text{ GeV} \). The next-to-leading order resonance Lagrangian, relevant in the odd-intrinsic parity sector of QCD, was formulated for the first time in \cite{9} and is of the form

\[ \langle 0 | \mathcal{O}_{\hat{X}} | \mathcal{O}_{\hat{X}} | 0 \rangle \neq 0 . \] (14)

The explicit calculations lead to the results \cite{5, 6}:

\[ \Pi_{VVP}(\lambda p)^2, (\lambda q)^2; (\lambda r)^2) = \frac{B_0 F^2}{2 \lambda^4} \frac{p^2 + q^2 + r^2}{p^2 q^2 r^2} + O \left( \frac{1}{\lambda^6} \right) , \] (15)

\[ \Pi_{VAS}(\lambda p)^2, (\lambda q)^2; (\lambda r)^2) = \frac{B_0 F^2}{2 \lambda^4} \frac{p^2 - q^2 - r^2}{p^2 q^2 r^2} + O \left( \frac{1}{\lambda^6} \right) , \] (16)

\[ \Pi_{AAP}(\lambda p)^2, (\lambda q)^2; (\lambda r)^2) = \frac{B_0 F^2}{2 \lambda^4} \frac{p^2 + q^2 - r^2}{p^2 q^2 r^2} + O \left( \frac{1}{\lambda^6} \right) . \] (17)

A detailed explanation of calculations within the OPE framework can be found in \cite{7, 8}.

So far, our discussion was rather of a mathematical nature. Hence, let us introduce the tools we use in our analysis. Dispersion representation of the Green functions which are order parameters of the chiral symmetry breaking enables us to make use of an information on the asymptotics both at the low and high energies and allows us to relate the unknown low energy constants (LECs) to the properties of the corresponding spectral functions in terms of the chiral sum rules. These are usually assumed to be saturated by the resonant states at low energies. This assumption connects the LECs to the phenomenology of resonances in the intermediate energy region, i.e. for energies \( M_\rho \leq E \leq 2 \text{ GeV} \). The next-to-leading order resonance Lagrangian, relevant in the odd-intrinsic parity sector of QCD, was formulated for the first time in \cite{9} and is of the form

\[ \mathcal{L}_R^{(6)} = \sum_X \sum_i \kappa_i^X \hat{O}_{\mu\nu\rho\beta}^{X} g^{\mu\nu\rho\beta} , \] (18)

where \( X \) stands for the single-resonance fields \( V, A, S, P \), double-resonance fields \( VV, AA, SA, SV, VA, PA, PV \) and triple-resonance fields \( VVP, VAS, AAP \). This Lagrangian contains 67 operators \( \hat{O}_{\mu\nu\rho\beta}^{X} \) in total and the same number of corresponding unknown coupling constants \( \kappa_i^X \). We try to determine the couplings using the following constraints: high-energy behavior (OPE), Brodsky-Lepage behavior of the transition formfactor, matching calculations in \( R \chi T \) with \( \chi PT \) or suitable inputs from experiments.

### 3 OPE for VVA Green function with two large momenta

Before we make the same attempt for the remaining VVA and AAA correlators, let us make use of an already known result of the two-point OPE for the VVA, where only two external momenta are large. In the standard definition of the VVA Green function, i.e. the correlator of two vector and one axial-vector current, one can factorize the symmetric tensor that comes from the traces over flavor space and the Lorentz part, which is restricted by the Ward identities into four terms, i.e.

\[ (\Pi_{VVA}(p, q, r))^{abc}_{\mu\nu\rho} = d^{abc} [ w_L E_{\nu(p)(q)} r_{\mu} + w_T^{(1)} \Pi_{\mu\nu\rho}^{(1)} + w_T^{(2)} \Pi_{\mu\nu\rho}^{(2)} + w_T^{(3)} \Pi_{\mu\nu\rho}^{(3)} ] , \] (19)
where $\Pi_{\mu
u}^{(i)} (i = 1, 2, 3)$ are transversal tensors defined in [10]. The longitudinal part proportional to the form factor $w_L$ is fixed by the anomaly, whilst $w_T^{(i)}$ are transversal form factors. In order to identify the unknown form factors $w_L, w_T^{(i)}$ we have calculated all possible Feynman diagrams at tree level that contribute to the VVA Green function and that are generated by the resonance Lagrangian [18]. Our calculations [11] lead to the results

$$w_L = \frac{N_c}{8\pi^2 r^2},$$

$$w_T^{(1)} = -\frac{2\sqrt{2}F_V[\kappa_{17}^V(p^2 + q^2 - 2M_V^2) - \sqrt{2}F_V\kappa_{3V}^V]}{(p^2 - M_V^2)(q^2 - M_V^2)},$$

$$w_T^{(2)} = -\frac{2\sqrt{2}F_V(p^2 - q^2)2\kappa_{12}^V + \kappa_{16}^V - \kappa_{17}^V)}{(p^2 - M_V^2)(q^2 - M_V^2)},$$

$$w_T^{(3)} = -\frac{2\sqrt{2}F_V(p^2 - q^2)}{(p^2 - M_V^2)(q^2 - M_V^2)}\left(2\kappa_{11}^V + 2\kappa_{12}^V + \kappa_{17}^V - \sqrt{2}F_A\kappa_{3A}^V\right)^2,$$}

$$w_T(Q^2) = -16\pi^2[w_T^{(1)}(-Q^2, 0, -Q^2) + w_T^{(3)}(-Q^2, 0, -Q^2)].$$

Be aware of the different notation here and in [10], although the definition (24) is defined here in order to be the same. An important fact is that the result for (24) up to $O(1/Q^8)$ was obtained from the OPE framework in AdS/QCD [12,13], in which the outcome reads

$$w_T(Q^2) = \frac{N_c}{Q^2} + \frac{128\pi^3\alpha_s\langle q\bar{q}\rangle^2}{9Q^6} + O\left(\frac{1}{Q^8}\right),$$

where $\chi$ is the magnetic susceptibility of the quark condensate - a detailed introduction and definition of this quantity can be found in [13]. Using (21) and (23), we simply obtain the formfactor (24) in the form

$$w_T(Q^2) = \frac{N_c}{M_V^2} + \frac{64\pi^2F_V}{M_V^2(Q^2 + M_V^2)}\left[Q^2\left(\sqrt{2}(\kappa_{11}^V + \kappa_{12}^V) + \frac{F_A\kappa_{3A}^V}{Q^2 + M_A^2}\right) - F_V\kappa_{3V}^V\right],$$

where we have already made a use of the known expression for the coupling constant $\kappa_{17}^V$ from the constraint $\kappa_{17}^V = -\frac{N_c}{64\sqrt{2}\pi^2F_V}$ for VVP Green function (see [9] for details). Now, we expand (26) into a series in terms of $Q^2$ up to $O(1/Q^8)$ and compare the coefficients of the given order with (25).
leads to the system of four equations, which can be easily solved:

\[
\begin{align*}
\frac{N_c}{64\pi^2 F_V} + \sqrt{2}(\kappa_{11}^V + \kappa_{12}^V) &= 0, \\
\frac{F_V \kappa_3^{VV} - F_A \kappa_5^{VA}}{M_V^2} + \sqrt{2}(\kappa_{11}^V + \kappa_{12}^V) &= -\frac{N_c}{64\pi^2 F_V}, \\
\frac{F_V \kappa_3^{VV} - F_A \kappa_5^{VA}}{M_V^2} + \sqrt{2}(\kappa_{11}^V + \kappa_{12}^V) - F_A \kappa_5^{VA} \frac{M_A^2}{M_V^4} &= 0, \\
\frac{F_V \kappa_3^{VV} - F_A \kappa_5^{VA}}{M_V^2} + \sqrt{2}(\kappa_{11}^V + \kappa_{12}^V) - F_A \kappa_5^{VA} \frac{M_A^2}{M_V^4} \left(1 + \frac{M_A^2}{M_V^2}\right) &= -\frac{2\pi\alpha\delta(\bar{q}q)^2}{9F_V M_A^4}.
\end{align*}
\]

From the first equation (27) we obtain the solution in the form (31). By using this solution in (28), we get a simple relation between the couplings \( \kappa_3^{VV} \) and \( \kappa_5^{VA} \) in the form \( \kappa_5^{VA} = \frac{F_V}{F_A} \kappa_3^{VV} \). From (29) we eventually obtain a specific form for both of these couplings, (32) and (33). The results are summarized here:

\[
\begin{align*}
\kappa_{11}^V + \kappa_{12}^V &= -\frac{N_c}{64\sqrt{2}\pi^2 F_V}, \\
\kappa_3^{VV} &= -\frac{N_c M_V^4}{64\pi^2 M_A^2 F_V^2}, \\
\kappa_5^{VA} &= -\frac{N_c M_V^4}{64\pi^2 M_A^2 F_V F_A}.
\end{align*}
\]

Having known the constraints above, we can substitute them in (30), which on the left side of the equation gives an expression \(-N_c M_A^2 M_V^2\) which obviously cannot be matched to the right side of the equation. Therefore, the system of equations (27)-(30) cannot be solved in order to satisfy all the equations at once. Hence, the obtained constraints (31)-(33) need not to be taken seriously, but more likely as a close approximation to reality.

Also, using the constraint for \( \kappa_{11}^V \) from the OPE for \( VVP \) Green function together with our result (32), we can extract relations for \( \kappa_2^{VV} \) and \( \kappa_3^{PV} \) (see [9] for details):

\[
\begin{align*}
\kappa_2^{VV} &= \frac{F^2}{64F_V^2} - \frac{N_c M_V^4}{512\pi^2 F_V^2 M_A^2}, \\
\kappa_3^{PV} &= -\frac{F^2}{32\sqrt{2}d_m F_V} \left[1 + \frac{N_c M_V^4}{8\pi^2 F^2} \left(\frac{M_V^2}{M_A^2} - 1\right)\right].
\end{align*}
\]

By the determination of (35) we can also obtain a relation for the deviation \( \delta_{BL} \) from the form of \( \kappa_3^{PV} \) if we take the Brodsky-Lepage behaviour [9, 14, 15] of the \( F_{\pi^0\gamma\gamma} \) form factor into account. Hence, the prediction is

\[
\delta_{BL} = \frac{N_c M_V^4}{8\pi^2 F^2} \left(\frac{M_V^2}{M_A^2} - 1\right) = -1.342.
\]

Now, a discussion involving the parameter \( \delta_{BL} \) is in order. Knowing the value (36), one can apply it to study a particular example that could be verified either by other theoretical consequences or experiments. In our case, a \( \pi^0\gamma\gamma \) form factor is a suitable tool, because the experimentally measured
is sensitive to the value of $\delta_{BL}$. The form factor (37) is depicted in figure 1 for our value $\delta_{BL} = -1.342$ and for two other values, based on [9]. The figure also contains experimentally obtained values of $F_{R\pi\gamma\gamma}^{R\chi\pi\gamma}(0, -Q^2; 0)$ from experiments BABAR [16], BELLE [17] and CLEO [18].

We can clearly see that the form factor (37) does not agree with the experimental data. To get a full notion, one should discuss first if we even have a sufficiently consistent theoretical model to describe such behaviour. In other words, is it sufficient not to add any other resonance fields and still have an agreement with the experiments? Obviously, not. The reason is that our form factor (37) for the value $\delta_{BL} = -1.342$ is very close to the behaviour of the form factor $F_{LMD}(0, -Q^2; 0)$ describing the lowest meson dominance (LMD) [19], [20]:

$$F_{LMD}(0, -Q^2; 0) = -\frac{N_c}{8\pi^2 F} \frac{M_V^2}{Q^2 + M_V^2} \left(1 + \frac{4\pi^2 F^2}{N_c M_V^4} Q^2 \right).$$

This means that it is not obviously sufficient to take only the lightest resonances into account and one thus needs to add heavier fields in order to get closer to the experimental data. To support our explanation, the LMD form factor (38) is also depicted in figure 1.

Figure 1. A plot of BABAR (green), BELLE (red) and CLEO (blue) data fitted with the form factor $F_{R\chi\pi\gamma}(0, -Q^2; 0)$ (37) using the modified Brodsky-Lepage condition. The full black line represents the form factor with $\delta_{BL} = -1.342$, the dashed line corresponds to $\delta_{BL} = -0.055$ (see [9]) and the dot-dashed line to $\delta_{BL} = 0$. The full brown line stands for the LMD form factor (38).
4 OPE for VVA and AAA Green functions with three large momenta

As we have seen above, the predicted value for \( \delta_{\text{BL}} \) is not consistent with the experimental data. Let us remind ourselves that such a prediction is based on the OPE with two large momenta. However, there is no physical argument that would prefer such a type of the OPE. Hence, one can try to calculate the OPE with all three momenta large and find out if the agreement between the results and experiment improves. However, such an approach is not that easy in the case of the VVA and AAA Green functions, because neither of these correlators have the leading order contribution to the OPE, i.e.

\[
\langle 0 | \sum_1^3 | 0 \rangle = 0 .
\]  

(39)

Therefore, one is required to include the contributions to higher orders by means of diagrams with gluons coupled to the quark fields. Such diagrams naturally lead to contributions of the higher QCD condensates. The scheme below illustrates the contributions of the quark condensate \((D = 3)\) in higher orders as well as the gluon condensate \((D = 4)\), the quark-gluon condensate \((D = 5)\), the four-quark condensate and the three-gluon condensate (both \(D = 6\)) \[21\]:

\[
\begin{align*}
D = 3 : & \quad + \\
D = 4 : & \quad + \\
D = 5 : & \quad + \\
D = 6 : & \quad + \\
\end{align*}
\]  

(40) \hspace{1cm} (41) \hspace{1cm} (42) \hspace{1cm} (43)

It is very important to mention that not all diagrams necessarily represent nontrivial contributions both for the VVA and AAA Green functions - some loops vanish due to the Furry theorem or due to a necessity to have the contributions Lorentz invariant. This study is now in progress \[21\].

5 Conclusion

In this article, we summarized the known results for the high-energy behaviour of Green functions within the OPE framework, relevant in the odd-intrinsic parity sector. We also presented our approach in order to evaluate the OPE for the VVA and AAA correlators for all momenta large.
