Abstract. The LHCb experiment is designed to study the properties and decays of heavy flavored hadrons produced in pp collisions at the LHC. The data collected enables precision spectroscopy studies of beauty and charm hadrons. The latest results on spectroscopy of conventional and exotic hadrons are reviewed.

1 Introduction

In the simple quark model, only two types of quark combinations are required to account for the existing hadrons, i.e. $q\bar{q}$ combinations form mesons, while baryons are made up of three quarks. However, in the quark model proposed by Gell-Mann and Zweig in 1960s [1] other SU(3) color-neutral combinations of quarks and gluons such as $gg$ glueballs, $q\bar{q}g$ hybrids, $qq\bar{q}$ tetraquarks, $q\bar{q}qq$ pentaquarks etc. are allowed. The world’s largest data sample of beauty and charm hadrons collected by LHCb provides great opportunities for studying the production and properties of heavy hadrons. The present document describes some recent results from LHCb in exotic and standard hadron spectroscopy.

2 The observation of pentaquarks in $\Lambda_b^0 \rightarrow J/\psi pK^-$

Evidences/observations of pentaquarks candidates were reported around 2005 by several experiments, always with low statistics and approximate statistical treatment of the data. For a summary and references see ref. [2]. High statistics searches gave negative results (see for example ref. [3]).

LHCb experiment studied the decay of $\Lambda_b^0 \rightarrow J/\psi pK^-$ [4]. A sample of 26,007 ± 166 signal candidates, on 5.4% background, within ±15 MeV of the $J/\psi pK^-$ mass peak has been selected using the full Run I dataset. An anomalous peaking structure in the $J/\psi p$ invariant mass spectrum was observed on the Dalitz plot. This structure can also be seen in the invariant mass projections shown in Fig. 1. If the peak structure observed in Fig. 1(b) represents a resonance strongly decaying into $J/\psi p$, the minimal valence quarks should be $c\bar{c}uuud$, a charmonium pentaquark state. A full six-dimensional amplitude fit with resonance invariant mass, three helicity angles and two differences between decay planes has been applied to describe the data. It allowed interference between the decays $\Lambda_b^0 \rightarrow J/\psi \Lambda^*$ and $\Lambda_b^0 \rightarrow P_c^+K^-$, with $\Lambda^* \rightarrow pK^-$ and $P_c^+ \rightarrow J/\psi p$, where $P_c^+$ indicates the pentaquark candidate. The amplitude model in the fit contains 14 well-defined $\Lambda^*$ states listed by Particle Data Group [5] and two $P_c^+$ states: $P_c(4380)^+$ and $P_c(4450)^+$. With a full amplitude analysis, the masses of these two states are measured to be $4380 ± 8$(stat) ± 29(syst) MeV and $4449.8 ± 1.7$(stat) ± 2.5(syst) MeV, with the widths

205 ± 18(stat) ± 86(syst) MeV and 39 ± 5(stat) ± 19(syst) MeV, respectively. The preferred spin-parity values are (3/2−, 5/2+), (3/2−, 5/2+) and (5/2−, 3/2−), where the first one is the Jπ assignment given by the best fit. This analysis has been extended with a model-independent approach [6] which gave consistent results. Results consistent with expectations have also been obtained from the amplitude analysis of the Cabibbo-suppressed decay Λb0 → J/ψpπ− [7].

3 Confirmation of resonant nature of Zc(4430)−

The Zc(4430)− state was first reported by the Belle collaboration [8] as a charged resonance structure in the ψ′π− invariant mass distribution in the decay B0 → ψ′K+π−. The BaBar collaboration could explain the enhancement as a reflection of the known K∗ states [9].

The LHCb experiment collected about 25,000 B+ signal events, a yield one order of magnitude larger than the BaBar or Belle datasets, and observed the Zc(4430)− with a significance larger than 13.9σ [10]. The LHCb collaboration performed both a model independent analysis as well as a full amplitude analysis. The projection of the fit including the Zc(4430)− state is shown in Fig. 2 and evidences a good description of the data. The measured parameters are M(Zc) = 4475 ± 7+15−25 MeV, Γ(Zc) = 172 ± 13+37−24 MeV. The Argand diagram of the Zc(4430)− amplitude (Fig. 2) shows the resonance behavior for the first time. The spin-parity was measured to be 1+, by excluding other hypotheses by at least 9.7σ. For a charged charmonium state, Zc(4430)− has a minimum quark content of c̅cud which clearly does not fit into the traditional quark model.

4 Study of B → J/ψφK

There has been a great deal of experimental and theoretical interest in J/ψφ mass structures in B+ → J/ψφK+ decays since the CDF collaboration presented 3.8σ evidence for a near-threshold X(4140) mass peak, with width Γ = 11.7 MeV [11]. Subsequent measurements resulted in a confusing experimental situation. LHCb experiment has reconstructed 4289 ± 151 B+ → J/ψφK+ decays, with roughly uniform efficiency and a relatively low background across the entire J/ψφ mass range [12]. A full amplitude analysis has been performed, including resonant contributions from K∗ resonances.

decaying to $\phi K^+$. Four resonant contributions in the $J/\psi \phi$ final state are found to contribute, whose parameters and quantum numbers are given in Table 1. The fit results are superimposed to the $J/\psi \phi$ mass spectrum in fig. 3. It can be noted that the X(4140) width is substantially larger than previously determined. The interpretation of these states is still an open issue.
5 Observation of five new $\Omega_c^0$ states

The spectroscopy of singly charmed baryons $cqq'$ is intricate. With three quarks and numerous degrees of freedom, many states are expected. Among the expected charmed baryon states the spectrum of $\Omega_c$ baryons, which have quark content $css$ and isospin zero, was largely unknown: only the $\Omega_c$ and $\Omega_c(2770)^0$, presumed to be the $J^P = 1/2^+$ and $3/2^+$ ground states, were observed.

The LHCb experiment has reconstructed a large ($\approx 10^6$ events) and high-purity (83%) sample of $\Xi_c^+K^-$ baryons, reconstructed in the Cabibbo-suppressed decay mode $pK^+\pi^-$ [13]. Surprisingly, in the $\Xi_c^+K^-$ mass spectrum, shown in Fig. 4, five new, narrow excited $\Omega_c$ states are observed: the $\Omega_c(3000)^0$, $\Omega_c(3050)^0$, $\Omega_c(3066)^0$, $\Omega_c(3090)^0$, and $\Omega_c(3119)^0$. The measured masses and widths are reported in Table 2. The data indicate also the presence of a broad structure around 3188 MeV that is fitted as a single resonance but could be produced in other ways, for example as a superposition of several states. In addition, the partially reconstructed decay $\Omega_c(3066)^0$, $\Omega_c(3090)^0$ and $\Omega_c(3119)^0$ in their possible decay to $\Xi_c^+$, $K^-$ are observed via their feed-down in the low mass region. This observation has generated large interest, especially for the presence of very narrow states, and many phenomenological models have been proposed, including the possibility of the presence of pentaquark states.

6 Observation of the double charmed baryon $\Xi_{cc}^{++}$

The constituent quark model of hadrons predicts the existence of three weakly decaying ground state $J^P = 1/2^+$ baryons with two charmed valence quarks: $\Xi_{cc}^{++}$ (ccd) and $\Xi_{cc}^{++}$ (ccu), which form an isospin doublet, and $\Omega_{cc}^{++}$ (ccs). The only previously published evidence of their existence comes from the observations of the $\Xi_{cc}^{++}$ baryon claimed by the SELEX collaboration [14]. They observed narrow peaking low statistics structures at a mean mass of $3518.7 \pm 1.7$ MeV in the mass spectra of $\Lambda_cK^-\pi^+$ and $pD^+K^-$. LHCb experiment has searched for double charmed baryon states using the decay mode $\Xi_{cc}^{++} \rightarrow \Lambda_cK^-\pi^+\pi^+$, with $\Lambda_c \rightarrow pK^-\pi^+$ (which has a 10% branching fraction) [15]. The $\Lambda_cK^-\pi^+\pi^-$ mass

spectrum is shown in Fig. 5(a) where a prominent signal can be observed. LHCb observes 313 ± 33
decays with a significance of > 12σ of a Ξ++cc state that has a mass of m(Ξ++cc) = 3621.40 ± 0.72(stat) ± 0.27(syst) ± 0.14(Λc) MeV and a width that is much smaller than experimental resolution and that is consistent with a particle that flies a significant distance before decaying. This is the first published observation of the Ξ++cc baryon. The published SELEX Ξ++cc state has a mass that is 103 ± 2 MeV smaller than the Ξ++cc state, so the two observations are inconsistent with being isospin partners. A consistent interpretation of the two observations may prove challenging.

7 Lifetime measurement of Ξ++cc

LHCb experiment has performed a Ξ++cc lifetime measurement relative to that of the Λb0 → Λc+π−π+π− which has the same topology [16]. An unbinned maximum likelihood fit to the background subtracted (using the sFit method) Ξ++cc decay time distribution has been performed using the function

\[ R(t) = \frac{f_{\Xi^{++}}}{f_{\Lambda^0_b}} \times \frac{\epsilon_{\Lambda^0_b}(t)}{\epsilon_{\Xi^{++}}(t)} = R(0) \times e^{-\frac{t}{\tau_{\Xi^{++}cc}}} \times \frac{1}{\tau_{\Lambda^0_b}} \]

where ε indicate the time dependent efficiencies. The fitted and background subtracted Ξ++cc lifetime distribution is shown in Fig. 5(b). The measured lifetime is

\[ \tau_{\Xi^{++}cc} = 0.256^{+0.024}_{-0.025} \pm 0.014 \text{ ps}, \]
in the lower end but compatible with the expected theoretical predictions. This confirms the weakly
decay nature of the newly discovered $\Xi_{cc}^{++}$ state.

8 Observation of a new $\Xi_{cc}^{++} \rightarrow \Xi_{cc}^{+}\pi^{+}$ decay mode

Searching for new decay modes is critical to understand the dynamics of weak decays of doubly heavy
baryons. The present LHCb analysis makes use of a data sample of $1.7\ fb^{-1}$ collected at 13 TeV [17].
The normalization channel $\Xi_{cc}^{++} \rightarrow \Lambda_{c}K^{-}\pi^{+}\pi^{+}$ is used and a significant peak ($5.9\sigma$) of
91 $\pm$ 20 events in the $\Xi_{cc}^{+}\pi^{+}$ mass spectrum (shown in Fig. 5(c)), where $\Xi_{cc}^{+} \rightarrow pK^{-}\pi^{+}$ is observed. The resulting mass
measurement is $m(\Xi_{cc}^{++}) = 3620 \pm 1.5\text{(stat)} \pm 0.4\text{(sys)} \pm 0.3\text{(\Xi_{cc}^{+}) MeV/c^2}$, consistent with the previous
measurement. The ratio of branching fractions is also measured as

$$\frac{\mathcal{B}(\Xi_{cc}^{++} \rightarrow \Xi_{cc}^{+}\pi^{+}) \times \mathcal{B}(\Xi_{cc}^{+} \rightarrow pK^{-}\pi^{+})}{\mathcal{B}(\Xi_{cc}^{++} \rightarrow \Lambda_{c}K^{-}\pi^{+}\pi^{+}) \times \mathcal{B}(\Lambda_{c} \rightarrow pK^{-}\pi^{+})} = 0.035 \pm 0.009\text{(stat)} \pm 0.003\text{(syst).}$$

9 Measurement of the $\Omega_{c}$ baryon lifetime

Charm baryon lifetimes are known much less precisely than charm meson ones. The expected lifetime
hierarchy should be: $\tau_{\Xi_{c}^{+}} > \tau_{\Lambda_{c}^{+}} > \tau_{\Xi_{c}^{0}} > \tau_{\Omega_{c}^{0}}$ and current measurements are consistent with this.
LHCb experiment makes use a sample of approximately $10^3$ semileptonic $\Omega_{c}^{0} \rightarrow \Omega_{c}^{0}\mu^{-}\bar{\nu}_{\mu}X$, with
the signal is shown in Fig. 6 together with the decay time
distribution. The fitted $\Omega_{c}^{0}$ lifetime is $\tau_{\Omega_{c}^{0}} = 268 \pm 21\text{stat} \pm 10\text{syst} \pm 2D^{+}$ fs, four times larger than and

inconsistent with the world average value of $(69 \pm 12)\ fs$. The present measurement produces the
modified lifetimes hierarchy as $\tau_{\Xi_{c}^{+}} > \tau_{\Omega_{c}^{0}} > \tau_{\Lambda_{c}^{+}} > \tau_{\Xi_{c}^{0}}$.

10 Observation of a new $\Xi_{b}^{-}$ resonance

A new $\Xi_{b}(6227)^{-}$ state is observed by LHCb decaying to both $\Xi_{b}^{0}\pi^{-}$ and $\Lambda_{b}^{0}K^{-}$ [19]. The analysis
makes use of a dataset of $1.0\ fb^{-1}$ at 7 TeV, $2.0\ fb^{-1}$ at 8 TeV and $1.5\ fb^{-1}$ at 13 TeV. Three inde-
pendent reconstructed decay chains are used: $\Xi_{b}(6227)^{-} \rightarrow \Lambda_{b}^{0}(\rightarrow \Lambda_{c}^{+}\pi^{-}K^{-})$, $\Xi_{b}(6227)^{-} \rightarrow \Xi_{b}^{0}(\rightarrow \Xi_{c}^{+}\mu^{-}X)\pi^{-}$, and $\Xi_{b}(6227)^{-} \rightarrow \Lambda_{b}^{0}(\rightarrow \Lambda_{c}^{+}\mu^{-}X)K^{-}$. In the case of semileptonic decays the missing $p_{\nu}$
momentum is reconstructed assuming a zero-mass particle that balances the momentum transverse to the direction of $\Lambda_b^0/\Xi_b^0$. The total invariant mass is then constrained to have the known $\Lambda_b^0/\Xi_b^0$ mass. The new resonance is observed in three different mass spectra as shown in Fig. 7 for the 13 TeV data. Similar signals are observed in the 7/8 TeV data. The new state could be identified as $\Xi_b(1P)$ or $\Xi_b(2S)$ states. Resonance resonance parameters are

$$m_{\Xi_b(6227)^-} = 6226.9 \pm 2.0 \text{stat} \pm 0.3 \text{syst} \pm 0.2(\Lambda_b^0) \text{ MeV}/c^2, \quad \Gamma_{\Xi_b(6227)^-} = 18.1 \pm 5.4 \text{stat} \pm 1.8 \text{syst} \text{ MeV}/c^2.$$
