1. Introduction

Development of compact vacuum-tube millimeter- and THz-band sources with 10-100 W output power would have a great potential for numerous applications such as high-data-rate wireless communications, security, spectroscopy, biomedical applications, etc. Among the vacuum tubes, microfabricated analogs of traveling-wave tube (TWT) amplifiers are the most promising. Over 50-W output power in G-band (0.22 THz) has recently been demonstrated [1,2].

Slow-wave structure (SWS) is a core part of a TWT serving to slow the electromagnetic wave down to the electron beam velocity. In this paper, we present the results of recent studies aimed at modeling and development of medium power TWTs with various SWS suitable for operation in millimeter and sub-THz frequency bands. Different types of TWTs are considered, such as folded-waveguide TWT, TWTs with sheet electron beam and dual-grating SWS, and TWTs with planar meander-line SWS on a dielectric substrate.

2. Folded-waveguide TWT

TWT with folded-waveguide (FW) SWS has numerous advantages due to its high coupling impedance, reasonably wide (~30%) bandwidth, relatively simple structure compatible with existing microfabrication technologies, thermal and mechanical robustness, and simple input/output coupling.

We designed and simulated FW TWTs operating at Q-band (38-54 GHz), V-band (48-90 GHz), and G-band (175-275 GHz). Electromagnetic parameters of the SWSs were calculated by using ANSYS HFSS simulator. FW SWS circuits at Q- and V-band were fabricated using CNC-milling machine. In Fig. 1, a picture of the 50-pitch Q-band SWS with input/output couplers is shown. Cold-test electromagnetic measurements of S-parameters of the circuits were performed using Keysight Technologies PNA N5227A vector network analyzer. Good transmission characteristics were measured. In particular, return loss (S11) is less than ~10 dB and transmission loss (S21) is about ~2 dB in the most part of the passband. Experimental measurements are in good agreement with numerical simulations using ANSYS HFSS.

In addition, small-signal and large-signal gain regimes of Q- and V-band FW TWT amplifiers driven by a 50-mA, 15-kV electron beam were simulated using the 1-D parametric code [3]. Parameters of the tubes were obtained, for which 30-40 dB small-signal gain and nearly 100 W saturated power are attained.

3. Sheet-beam TWT dual-grating SWS

Using high-aspect-ratio sheet electron beams allows substantial reduce of current density and facilitates beam focusing and transportation in a narrow beam tunnel. In [3,4], we studied feasibility of a 0.2-THz sheet-beam TWT amplifier with a staggered grating SWS. An electron gun with a 0.7×0.1 mm$^2$ thermionic cathode producing intensive sheet electron beam with over 120 A/cm$^2$ current density has been developed [3,4]. However, such a gun can operate only in a short-pulse mode with 10 us pulse duration and 2000 off-duty cycle. At the same time, the required focusing magnetic field is as high as 11.2 T.

In order to overcome the problems mentioned above, we designed the electron-optic system (EOS) with a converging sheet electron beam having 10-times compression in vertical direction using the method of synthesis described in [5]. This allows a significant reduce of the beam thickness as well as of the cathode load and focusing magnetic field (0.8 T). Schematic of the electron gun is presented in Fig. 2. The design was verified by 3-D simulation using LORENTZ-3EM simulator [6]. The results are in a fairly good agreement, except that the beam thickness obtained in 3-D analysis is somewhat higher than expected (~75 um) that can be attributed to thermal and angle spread of the emitted electrons.

The gun was fabricated and up to 140-mA beam current was measured.
The developed SWSs provide high slow-down factor \((c/v_p \approx 7+9)\) and thus are suitable for operation with a low-voltage \((3+5 \text{ kV})\) electron beam. Small-signal and large-signal gain characteristics of the TWT driven by a 100-mA sheet electron beam were simulated. For a 1-cm-length SWS, the peak gain is about 15-20 dB. Owing to strong dispersion of the meander-line SWS, the bandwidth of the amplifier is rather narrow \((2-3 \text{ GHz})\). However, the central frequency may be easily tuned in a wide range by varying the beam voltage. The simulations predict over 60 W output power at saturation.
